Trombosis parcial segmentaria de cuerpo cavernoso: reporte de un caso, imágenes y factores de riesgo.

Pablo Avaria, Michael Hirsch, Alejandro Bustos, Marcos Tapia.

Abstract

Partial segmental thrombosis of the corpus cavernosum (PSTCC) is an extremely rare disease, mainly affecting younger men, and with an aetiology that is not completely understood. It is characterised by thrombosis of the proximal portion of the corpus cavernosum, almost always unilateral, generating perineal pain. In the current case report, a complete description of the risk factors and imaging associated with this pathology is presented.
